

- 1) MongoDB: While setting up MongoDB, I found out that we can use MongoDB Atlas ~~Atlas~~ which is basically a cloud database and we can connect ~~to~~ our app to it using a connection URL, also it is free to a certain extent.
- 2) Prisma: While defining a model in prisma and using it ~~to~~ for my post method, it found that prisma by default changes the model name in camel case. It did something like ToDo and changed it to todo (which using the model) in my post method. Also use findMany() and create() methods.
- 3) ~~1.~~ No Query: Also while going through tutorials I was searching for queries (query statement) in code and later realized that MongoDB is a NoSQL database and we can directly create collections using prisma.

## 4) Import and require

While setting up my express project i found that we were using `require("")` instead of `import` which can be fixed by inserting `type: "module"` in `package.json` file. `Import` needs to be on top of the file but `require` can be used anywhere and `import` is basically a newer version. `Require` was used before ES modules were supported.

## 5) CORS

Cross Origin Resource Sharing.

While trying to integrate the backend api, i faced cors error in my frontend side. ~~which~~ CORS is a security feature implemented by browsers that restrict how web pages can req to diff domain. So i installed cors package in my backend and enabled origin `'http://localhost:5173'` which is default for react.
